

Step 1 -- Freeze Δ, A, B, C (necessity test)

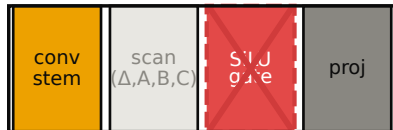

conv stem scan (Δ, A, B, C) SiLU gate proj

BM3-frozen

Step 2 -- Remove gate (localise)

frozen – gate

Step 3 -- Add gate to S4D (sufficiency test)

S4D + gate
+ added

$\Delta(\text{BM3} - \text{frozen}) \leq 5\text{pp}$ (CI incl. 0);
frozen $\gg$ S4D (+14–20pp)
→ Δ, A, B, C not primary

gate removal: –9 to –24pp,
to $\approx$ S4D level or below
→ gate is necessary here

recovery ratio $R = 0.17\text{--}0.20$
(< 0.3 'insufficient' bin)
→ this graft recovers little

Conditional on this block, testbed and budget: the gate's benefit depends strongly on the host.
